# **Computer basics**

**Subject teacher : Assistant Professor Firas Ali Mohammed**

## GETTING STARTED

### ***Class Overview***

This is a class for very beginning computer users. You are not expected to have ANY experience with computers. If you've never touched a computer before, this is the right place for you.

We will be using personal computers (PC) running the Microsoft Windows operating system. You may have heard these words before, but if not, don't worry. We'll cover their meanings later in the class.

Don't get discouraged! Remember: Practice makes perfect and everyone starts out as a beginner. Using the keyboard and mouse may be challenging at first, but it will become easier the more you use them. **Note:** The mouse is intended for you to use with your right hand, regardless of whether or not you are right-handed. This shouldn't be an issue in class, but if the mouse is uncomfortable for you, let your instructor know.

Please let the instructor know if you have questions or concerns before the class, or as we go along.

### ***What You Will Learn***

Identify major computer components	Understand the basics of how computers work	Differentiate between software and hardware
Turn a computer on	Log on to a computer	Identify the computer desktop
Change the appearance of the desktop	Use the keyboard	Use and understand the different functions of the mouse
Basics of the Microsoft Windows operating system	Utilize the Start Menu in Microsoft Windows	Utilize the Taskbar in Microsoft Windows
Buy a computer	Buy other software and programs	Differentiate between logging off and shutting down
Shut down the computer	Find more help	

## BASIC COMPUTER SKILLS

On any given day, you will encounter computer systems in much of what you do, even if you don't realize it. The television channels you watch, the radio stations that you listen to, the car that you drive in, and even the cash register at the local grocery store are all controlled in some way by computer systems! They help us perform tasks, keep track of information, and even control the airplanes that fly above us. Throughout the course of this class, you will learn about how computers work, how to perform simple tasks, and more.

### *Anatomy of a Computer*

As with most products, computers are designed in a variety of ways. There are, however, major similarities regardless of the brand (e.g., Dell, Apple, Acer, HP, Lenovo) of the computer. There are two main types of computers, desktops and laptops. However, all computers have the following components:

### **THE MONITOR**

The monitor looks like a television screen and is where you see what is happening on your computer. By using shadows and graphics with over a million different colors, much of what you see will appear 3-dimensional. Think of this as the 'face' of the computer.

### **THE CPU (Central Processing Unit)**

The CPU houses the machinery that allows your computer to work. Think of this as the 'brains' of the computer. This component looks very different in desktops and laptops, but it works the same.

### **THE KEYBOARD**

The keyboard is one of two ways to interact with your computer. The keys should mostly mimic a traditional typewriter.

### **THE MOUSE**

This is the other way to interact with your computer. Most mice have two buttons—a right and a left button—and a scrolling wheel.

**Tablet Computers**

A type of mobile computer called a **tablet**. Tablets have all of the main computer parts in one unit. Generally, a tablet comes with no physical mouse or keyboard and most of the input is done by touching the screen. Additional accessories such as keyboards are normally available for purchase to help make the tablet easier to use. Tablets are convenient to use for traveling since they are small and easy to carry.

***How Computers Work*****Hardware / Software**

Computers use both hardware and software to perform their work. Think of hardware as the physical pieces of a computer—the monitor, the CPU, all the pieces and parts inside the CPU, the mouse, the keyboard, etc. Software, on the other hand, consists of programs that we use to interact with the computer. You can't physically touch software like you can the keyboard, but you can still interact with it. A word processing program like Microsoft Word is a piece of software that you could use to type a grocery list. Games that you play on your computer are also considered software—it doesn't have to be work-related!

**Information / Data**

Computers are designed to work with a type of information commonly referred to as "data." Data comes in many forms, whether it is written data (such as a letter to a friend), audio data (like a song), video data (like a popular movie or DVD), and more. Certain types of software programs work with different types of data. For example, iTunes works primarily with audio data, while Microsoft Word, a word processing program, works primarily with written data.

The keyboard is just one of the ways in which you can create, interact with, and modify data. There are many ways to get data off of the computer, such as printing it out on paper, copying it to a CD or flash drive, or publishing it to the Internet.

### **"My Computer is Possessed!"**

It is a common misconception that computers have "a mind of their own."

Although computers can perform certain tasks much more easily and faster than humans (like counting, performing mathematical calculations, etc.), they are, in the end, machines and can't think for themselves. It is safe to say that the computer cannot do anything that you do not tell it to do. Remember that you are in control of the computer, in the same way that you are in control of your car. Your car won't move until you press your foot on the accelerator, and it won't stop until you press the brake. Computers work in the same way.

### **Keeping Your Computer Healthy**

In the end, computers are machines just like any other. Sometimes, although not often, they may malfunction, become stuck (or "frozen"), or may have a part that breaks and needs to be replaced. Just like your car or lawnmower, computers need to be maintained. Keeping your virus software up-to-date, installing updates for your operating system (e.g., Windows updates), and refraining from installing unnecessary programs will keep your computer running smoothly and efficiently for a longer period of time. Consider computer maintenance like oil changes in cars – necessary for the machines to run as long as possible!

### **Key Facts About Computers**

- A computer does *not* need to access the Internet in order to run properly.
- The Internet is a way of connecting to other computer users. You can connect to the internet using a phone line, a cable connection, or by using a wireless connecting device (wi-fi). For most home computer users, this is a paid service, though you can use the Internet for free in some public locations, like the library or a coffee shop.
- A computer will be able to perform most common functions (play music, type documents, edit pictures) and run programs without an Internet connection. However, to view a web page or send an e-mail, you will need an Internet connection.
- A computer needs an Operating System in order to work, though any new computer that you purchase will come with an operating system already installed. The most common operating systems are Microsoft Windows and Macintosh OS X.

## OPERATING SYSTEMS

### *The Operating System (OS)*

Computers without operating systems are exactly like televisions without a signal: They will turn on, but you will be looking at a blank screen with no hope of interacting with it (*the lights are on, but nobody's home*)! The most popular operating system is "Microsoft Windows," and it is utilized by most personal computer (PC) users. It is what you are using today in class. If you think of the CPU as the "brains" of the computer, the operating system **acts as the nervous system of the computer**, connecting the CPU to all the computer programs. The operating system allows you to run other programs, work on projects, and do basically everything else that computers are capable of. There are many different versions of Microsoft Windows, and a new version is released every couple of years (just like car models).

There are other operating systems as well. Apple manufactures a computer called a Macintosh, or Mac. Macs use an operating system called "Mac OS X" which, while it looks very different from Microsoft Windows, runs using the same basic principles. While fewer people use Macs than PCs, schools often use Macs, as well as people who work with graphic design and video and image editing. As a general rule, Macs tend to be more expensive than PCs.

You shouldn't ever need to mess with the operating system. It should run correctly and without error for as long as you have your computer. In fact, if you ever take your computer in for a repair, the technician will be looking primarily at your operating system (not your programs), in the same way that a mechanic will look at your car's engine.

The operating system of your computer is so important, that any computer you buy will be sold with one already installed and ready to go (so outside of choosing between a PC and a Mac, you don't really need to worry about the operating system except to make sure you get the newest or most appropriate version). In addition, popular software programs are also often already installed on computers, so all you have to do is plug your computer in and go!

Computer Manufacturer (e.g.  
Lenovo)  
Computer is called a **PC**  
Operating System is **Windows**

Apple  
Computer is called a **Macintosh**  
(**Mac**)  
Operating System is **OS X**

### ***Turning On the Computer and Logging On:***

#### **Turning the Computer On**

Let's get started! As you sit down at your desk, you can assume that your computer system is one of three states:

- **OFF:** This is exactly what it sounds like: The computer is off, and no parts are running or working. The monitor is black (no images), there is no "whirring" sound from the CPU, and the computer is unresponsive to mouse movements or pressing keys on the keyboard. The power button (if it lights up) should not be lit up.
- **ON:** When a computer is on, you should see images on the monitor, possibly hear a "whirring" noise coming from the CPU (hopefully not too loud!), and the pointer on the screen (the small white arrow) should respond when you move the mouse.
- **SLEEP MODE:** Most computers have a mode called "Sleep," in which the computer is on, but has assumed an energy-efficient, minimal power mode. To "wake" the computer, simply move the mouse around or press the space bar on the keyboard, and it will "wake up" and return to the exact same place that it was when it went to sleep. In other words, if you were using a word processing program and the computer went to sleep, it would return to exactly what you were working on when it wakes up.

To turn a computer on, simply press the power button once (no need to hold the button—just press and release). We will go over how to turn off a computer later in this handout.

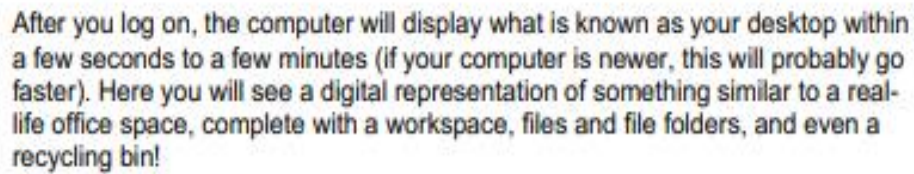

## Logging On

Once you turn the computer on, the computer will go through a series of automated tasks before it is ready for you to interact with it; this process is called "startup." This process will last between one and two minutes. If the computer is not working correctly, you may see an error message during startup. If the computer is performing as it should, however, you will probably see one of the following screens:

This is called a "Log On" window, and it means that the computer is password protected. If you do not see this window upon starting the computer, you can assume that your computer is NOT password-protected and may be used by anyone. To log on, you simply enter your user name and password. If you are using a public library computer, this could be your library card number.

## THE KEYBOARD AND MOUSE

### *Keyboard Commands*

In order to use your computer effectively, you must interact with it using both the mouse and the keyboard. The above image of a keyboard may closely resemble (if it is not identical to) the keyboard in front of you; learning the function of just a few keys will help you to interact better with your computer and individual programs. The following is a list of commonly used keys that have special functions (keep in mind that key functions can change depending on which program you are using):

1. **Backspace:** This key deletes letters backward ( ).
2. **Delete:** This key deletes letters forward ( ).
3. **Shift:** This key, when pressed WITH another key, will perform a secondary function.
4. **Spacebar:** This key enters a space between words or letters.
5. **Tab:** This key will indent what you type, or move the text to the right. The default indent distance is usually  $\frac{1}{2}$  inch.
6. **Caps Lock:** Pressing this key will make every letter you type capitalized.
7. **Control (Ctrl):** This key, when pressed WITH another key, performs a shortcut.
8. **Enter:** This key either gives you a new line, or executes a command (pressed in a word processing program, it begins a new line).
9. **Number Keypad:** These are exactly the same as the numbers at the top of the keyboard; some people find them easier to use in this position.
10. **Arrow Keys:** Like the mouse, these keys are used to navigate through a document or page.

## ***The Mouse***

While the keyboard is primarily used to insert/input and manipulate text and numbers on a computer, the mouse is used mostly for navigating around the screen. Mice come in a variety of shapes and sizes. Some of the strangest-looking mice often look that way because they are designed to be more ergonomic than traditional mice.

There are traditional mice...

unusually shaped mice...

stylish mice...

complicated mice...

The type of mouse that you choose to use is totally based on your preference—if you want a fancy mouse, that's fine; if you prefer a simple mouse, that's OK too. Each mouse, however different it may be, has similar functions. As you can see on the "traditional" model above, a traditional mouse has two buttons with a wheel between them (gray) that spins, called a "scroll wheel." Both buttons can perform separate functions, and are referred to by which side of the mouse they are located on.

Pressing the LEFT mouse button is called "left-clicking," while pressing the RIGHT mouse button is called "right-clicking."

Left-clicking is used far more often than right clicking. For now, know that left-clicking is used to select or click on something, while right-clicking presents additional menu options.

### ***Left-Clicking, Double-Clicking and Right-Clicking***

One of the most difficult things to learn when first beginning to use a computer, is how to use the mouse. It takes coordination, precision, and patience. Fortunately, **the more you practice, the easier it will become!**

The mouse symbol, or **pointer**, that appears on the computer screen will change its look and function depending on what it is near or hovering over.

 Your mouse pointer will most often look like an arrow

 When your mouse pointer is over an internet link, it will look like a pointing hand

● When your mouse pointer is over a place where you can type, it will look like an I-beam

 When your computer is busy or 'working,' your mouse pointer may look like an hourglass or a spinning circle.

There are actually many different pointers (though these are the most common), and they will change automatically depending on what task you are trying to perform.

The **buttons** on the mouse may also have different functions, depending on which program you are using. If you are working in Microsoft Word, for example, the mouse will offer options related to Microsoft Word. Conversely, if you are working in Microsoft Excel, the mouse will offer options related to Microsoft Excel, and so on.

For now, remember these rules:

1. The **LEFT** mouse button **SELECTS** items.
2. The **RIGHT** mouse button **GIVES YOU MORE OPTIONS**.
3. Double-Clicking the **LEFT** mouse button **EXECUTES** options (for example, you can open a program by double-clicking an icon on the desktop).
4. Double-Clicking the **RIGHT** mouse button **does not do anything**.

Vista," and "Windows 7." Many people continue to use Windows Vista and Windows 7, even though newer versions have been released. It is important to know that there are different versions of Windows, because different features (such as the Start Menu discussed above) may look different in different versions.

### **Managing "Windows"**

Microsoft Windows is called "Windows" for a reason. Programs appear on your screen as "Windows" (rectangular shapes) and are laid 3-dimensionally on top of one another (see image at right), just like on a real desktop. The desktop is your work surface, and all of your open windows appear on top of it.

If you can see a window, that means the program is *open* and running. It is possible to make the window bigger, smaller, or close it using the buttons in the top right corner of any window.

**Minimize:** Left-click this button to shrink the window down to a small button that will appear in the task bar (see below).

**Maximize:** Left-click this button to make the window as large as it can be—it should take up your entire screen.

**Restore Down:** Left-click this button to make the window smaller without minimizing it.

**Close:** Left-click this button to close the window. The program will close and stop running. Make sure you save your work first!

Microsoft Windows is capable of running more than one program at once. In other words, you can write a letter in Microsoft Word, **while** surfing the Internet **while** using Microsoft Excel **while** checking your e-mail and so on! This is called "multi-tasking" and is a feature of all computers. However, with all of these things going on at once, how do you keep track of them all? The **Taskbar**, which is the bar that spans across the bottom of your screen next to the Start Menu, is designed to help you keep track of all of your programs. It looks like this:

In the illustration above, there are several programs running. Each program that is open is represented by a "button" on the Taskbar. To use one of the programs that is "open," simply left-click on it once to bring it up to the top of the screen. The taskbar is modeled after what might happen in real life: You are reading the newspaper, and you put it down to pick up your favorite book. You didn't throw it out or destroy it, you simply **set it aside**. This way, you can pick up right where you left off once you are done reading your book. The taskbar works the same way, but with software programs, not books.

### ***Buying a Computer***

When considering the merits of a computer, it's important to consider the following questions:

- How fast can the computer perform tasks?
- How much information (or data) can it store?
- How many programs (i.e. software) can it run simultaneously?

Buying a computer is a big decision, and can be quite expensive. It is a good idea to do some research before buying a computer to find out what would work best for your needs, what computers have performed well for others, and what models are within your price range. Asking for help finding this information at the reference desk of your local library is a good place to start. In addition, here are some websites you might want to check out:

- <http://www.consumerreports.org/> (under electronics, select "Computers")
- [http://www.ehow.com/how\\_3038\\_buy-computer.html](http://www.ehow.com/how_3038_buy-computer.html)
- [http://www.pcworld.com/article/125649/how\\_to\\_buy\\_a\\_desktop\\_pc.html](http://www.pcworld.com/article/125649/how_to_buy_a_desktop_pc.html)
- Personal computer companies:
  - <http://www.dell.com/>
  - <http://www.lenovo.com/>
  - <http://www.hp.com/>

### ***Other Programs and Software***

Although there may be lots of software pre-installed on your computer when you buy it, there are many more programs available for you to download or buy, from educational games for children to photo editing software to professional programming software. If you are interested in a particular type of software, here are some suggested Web sites to check out:

### Logging Off vs. Shutting Down

By contrast, when you click **Shut Down**, it is like turning a car's ignition off. You need to make sure that processes and programs are properly ended and shut down before pushing the shutdown button, just as with a car you have to turn off the ignition before pulling out the key. Click the Start button, then click Shut Down. ***Do not press the power button to turn off your computer!***

After you have clicked Shut Down, your computer will begin a shut-down process in which it saves things you have been working on, and ends all programs that are running. You may see a window that says, "Windows is shutting down." When the computer is done shutting down, the screen will go black, and the computer tower will stop making any noise. It is now shut down. It is *not* necessary to press the power button—your computer will turn off automatically.

### ***Finding More Help***

If you ever find that you need help while using your computer, you can left-click the **Start** button, and then click “Help and Support.”

In addition, most programs on your computer will also have an individual help feature. The Help function may be available from a Help menu at the top of the window, or by clicking a button. Help buttons are usually located in the top-right corner of the window, and may look like a question mark. Help menus often have a search function or pre-prepared FAQs. Most programs also have 1-800 numbers to connect with a technician.

### ***Vocabulary to Know***

After taking this course, you should be familiar with the following basic computer words. If you don't recognize one, please ask your instructor!

- Desktop
- Laptop
- Keyboard
- Mouse
- CPU
- Operating System
- Internet
- Start Menu
- Logging on
- Logging off
- Shut down
- Mac
- PC
- Taskbar
- Pointer or cursor
- Left click
- Right click

## **I. Computer: Definition**

A computer is a machine that can be programmed to manipulate symbols. Its principal characteristics are:

- It responds to a specific set of instructions in a well-defined manner.
- It can execute a prerecorded list of instructions (a program).
- It can quickly store and retrieve large amounts of data.

Therefore, computers can perform complex and repetitive procedures quickly, precisely and reliably. Modern computers are electronic and digital. The actual machinery (wires, transistors, and circuits) is called hardware; the instructions and data are called software. All general-purpose computers require the following hardware components:

- Central processing unit (CPU): The heart of the computer, this is the component that actually executes instructions organized in programs ("software") which tell the computer what to do.
- Memory (fast, expensive, short-term memory): Enables a computer to store, at least temporarily, data, programs, and intermediate results.
- Mass storage device (slower, cheaper, long-term memory): Allows a computer to permanently retain large amounts of data and programs between jobs. Common mass storage devices include disk drives and tape drives.
- Input device: Usually a keyboard and mouse, the input device is the conduit through which data and instructions enter a computer.
- Output device: A display screen, printer, or other device that lets you see what the computer has accomplished.

In addition to these components, many others make it possible for the basic components to work together efficiently. For example, every computer requires a bus that transmits data from one part of the computer to another.

## **II. Computer sizes and power**

Computers can be generally classified by size and power as follows, though there is considerable overlap:

- Personal computer: A small, single-user computer based on a microprocessor.
- Workstation: A powerful, single-user computer. A workstation is like a personal computer, but it has a more powerful microprocessor and, in general, a higher-quality monitor.
- Minicomputer: A multi-user computer capable of supporting up to hundreds of users simultaneously.
- Mainframe: A powerful multi-user computer capable of supporting many hundreds or thousands of users simultaneously.
- Supercomputer: An extremely fast computer that can perform hundreds of millions of instructions per second.

### ***Supercomputer and Mainframe***

Supercomputer is a broad term for one of the fastest computers currently available. Supercomputers are very expensive and are employed for specialized applications that require immense amounts of mathematical calculations (number crunching). For example, weather forecasting requires a supercomputer. Other uses of supercomputers scientific simulations, (animated) graphics, fluid dynamic calculations, nuclear energy research, electronic design, and analysis of geological data (e.g. in petrochemical prospecting). Perhaps the best known supercomputer manufacturer is Cray Research.

Mainframe was a term originally referring to the cabinet containing the central processor unit or "main frame" of a room-filling Stone Age batch machine. After the emergence of smaller "minicomputer" designs in the early 1970s, the traditional big iron machines were described as "mainframe computers" and eventually just as mainframes. Nowadays a Mainframe is a very large and expensive computer capable of supporting hundreds, or even thousands, of users simultaneously. The chief difference between a supercomputer and a mainframe is that a supercomputer channels all its power into executing a few programs as fast as possible, whereas a mainframe uses its power to execute many programs concurrently. In some ways, mainframes are more powerful than supercomputers because they support more simultaneous programs. But supercomputers can execute a single program faster than a mainframe. The distinction between small mainframes and minicomputers is vague, depending really on how the manufacturer wants to market its machines.

### ***Minicomputer***

It is a midsize computer. In the past decade, the distinction between large minicomputers and small mainframes has blurred, however, as has the distinction between small minicomputers and workstations. But in general, a minicomputer is a multiprocessing system capable of supporting from up to 200 users simultaneously.

### ***Workstation***

It is a type of computer used for engineering applications (CAD/CAM), desktop publishing, software development, and other types of applications that require a moderate amount of computing power and relatively high quality graphics capabilities. Workstations generally come with a large, high-resolution graphics screen, at large amount of RAM, built-in network support, and a graphical user interface. Most workstations also have a mass storage device such as a disk drive, but a special type of workstation, called a diskless workstation, comes without a disk drive. The most common operating systems for workstations are UNIX and Windows NT. Like personal computers, most workstations are single-user computers. However, workstations are typically linked together to form a local-area network, although they can also be used as stand-alone systems.

N.B.: In networking, workstation refers to any computer connected to a local-area network. It could be a workstation or a personal computer.

### ***Personal computer:***

It can be defined as a small, relatively inexpensive computer designed for an individual user. In price, personal computers range anywhere from a few hundred pounds to over five thousand pounds. All are based on the microprocessor technology that enables manufacturers to put an entire CPU on one chip. Businesses use personal computers for word processing, accounting, desktop publishing, and for running spreadsheet and database management applications. At home, the most popular use for personal computers is for playing games and recently for surfing the Internet.

Personal computers first appeared in the late 1970s. One of the first and most popular personal computers was the Apple II, introduced in 1977 by Apple Computer. During the late 1970s and early 1980s, new models and competing operating systems seemed to appear daily. Then, in 1981, IBM entered the fray with its first personal computer, known as the IBM PC. The IBM PC quickly became the personal computer of choice, and most other personal computer manufacturers fell by the wayside. P.C. is short for personal computer or IBM PC. One of the few companies to survive IBM's onslaught was Apple Computer, which remains a major player in the personal computer marketplace. Other companies adjusted to IBM's dominance by building IBM clones, computers that were internally almost the same as the IBM PC, but that cost less. Because IBM clones used the same microprocessors as IBM PCs, they were capable of running the same software. Over the years, IBM has lost much of its influence in directing the evolution of PCs. Therefore, after the release of the first PC by IBM the term PC increasingly came to mean IBM or IBM-compatible personal computers, to the exclusion of other types of personal computers, such as Macintoshes. In recent years, the term PC has become more and more difficult to pin down. In general, though, it applies to any personal computer based on an Intel microprocessor, or on an Intel-compatible microprocessor. For nearly every other component, including the operating system, there are several options, all of which fall under the rubric of PC

Today, the world of personal computers is basically divided between Apple Macintoshes and PCs. The principal characteristics of personal computers are that they are single-user systems and are based on microprocessors. However, although personal computers are designed as single-user systems, it is common to link them together to form a network. In terms of power, there is great variety. At the high end, the distinction between personal computers and workstations has faded. High-end models of the Macintosh and PC offer the same computing power and graphics capability as low-end workstations by Sun Microsystems, Hewlett-Packard, and DEC.

### ***III. Personal Computer Types***

Actual personal computers can be generally classified by size and chassis / case. The chassis or case is the metal frame that serves as the structural support for electronic components. Every computer system requires at least one chassis to house the circuit boards and wiring. The chassis also contains slots for expansion boards. If you want to insert more boards than there are slots, you will need an expansion chassis, which provides additional slots. There are two basic flavors

of chassis designs—desktop models and tower models—but there are many variations on these two basic types. Then come the portable computers that are computers small enough to carry. Portable computers include notebook and subnotebook computers, hand-held computers, palmtops, and PDAs.

#### **Tower model**

The term refers to a computer in which the power supply, motherboard, and mass storage devices are stacked on top of each other in a cabinet. This is in contrast to desktop models, in which these components are housed in a more compact box. The main advantage of tower models is that there are fewer space constraints, which makes installation of additional storage devices easier.

#### **Desktop model**

A computer designed to fit comfortably on top of a desk, typically with the monitor sitting on top of the computer. Desktop model computers are broad and low, whereas tower model computers are narrow and tall. Because of their shape, desktop model computers are generally limited to three internal mass storage devices. Desktop models designed to be very small are sometimes referred to as **slim line models**.

#### **Notebook computer**

An extremely lightweight personal computer. Notebook computers typically weigh less than 6 pounds and are small enough to fit easily in a briefcase. Aside from size, the principal difference between a notebook computer and a personal computer is the display screen. Notebook computers use a variety of techniques, known as flat-panel technologies, to produce a lightweight and non-bulky display screen. The quality of notebook display screens varies considerably. In terms of computing power, modern notebook computers are nearly equivalent to personal computers. They have the same CPUs, memory capacity, and disk drives. However, all this power in a small package is expensive. Notebook computers cost about twice as much as equivalent regular-sized computers. Notebook computers come with battery packs that enable you to run them without plugging them in. However, the batteries need to be recharged every few hours.

#### **Laptop computer**

A small, portable computer -- small enough that it can sit on your lap. Nowadays, laptop computers are more frequently called notebook computers.

#### **Subnotebook computer**

A portable computer that is slightly lighter and smaller than a full-sized notebook computer. Typically, subnotebook computers have a smaller keyboard and screen, but are otherwise equivalent to notebook computers.

#### **Hand-held computer**

A portable computer that is small enough to be held in one's hand. Although extremely convenient to carry, handheld computers have not replaced notebook computers because of

their small keyboards and screens. The most popular hand-held computers are those that are specifically designed to provide PIM (personal information manager) functions, such as a calendar and address book. Some manufacturers are trying to solve the small keyboard problem by replacing the keyboard with an electronic pen. However, these pen-based devices rely on handwriting recognition technologies, which are still in their infancy. Hand-held computers are also called PDAs, palmtops and pocket computers.

### **Palmtop**

A small computer that literally fits in your palm. Compared to full-size computers, palmtops are severely limited, but they are practical for certain functions such as phone books and calendars. Palmtops that use a pen rather than a keyboard for input are often called hand-held computers or PDAs. Because of their small size, most palmtop computers do not include disk drives. However, many contain PCMCIA slots in which you can insert disk drives, modems, memory, and other devices. Palmtops are also called PDAs, hand-held computers and pocket computers.

### **PDA**

Short for personal digital assistant, a handheld device that combines computing, telephone/fax, and networking features. A typical PDA can function as a cellular phone, fax sender, and personal organizer. Unlike portable computers, most PDAs are pen-based, using a stylus rather than a keyboard for input. This means that they also incorporate handwriting recognition features. Some PDAs can also react to voice input by using voice recognition technologies. The field of PDA was pioneered by Apple Computer, which introduced the Newton Message Pad in 1993. Shortly thereafter, several other manufacturers offered similar products. To date, PDAs have had only modest success in the marketplace, due to their high price tags and limited applications. However, many experts believe that PDAs will eventually become common gadgets. PDAs are also called palmtops, hand-held computers and pocket computers.
